Keys the "Language" of the program.Morphological and Biochemical Analyses of Mesenchymal Stem Cells and Dermal Fibroblasts of Three Different Ethnic Origin in Normal Human Skin. Mesenchymal stem cells (MSCs) are multipotent progenitor cells that can be isolated from a variety of tissues. We isolated and characterized MSCs from dermal fibroblasts (DFs) of three normal human skin specimens taken from Caucasian (CV), Japanese (Jap), and Chinese (C) patients. We found that both CV-DFs and Jap-DFs had a greater expression of cell markers with a surface phenotype of mesenchymal cells (CD73, CD90, and CD105) than CV-DFs. However, C-DFs had greater expression of cell markers with a surface phenotype of epithelial cells (cytokeratin, CD326, CD133, and EpCAM) than CV-DFs. In addition, CV-DFs expressed higher levels of two stemness factors, octamer-binding transcription factor 4 (Oct4) and Kruppel-like factor 4 (Klf4), than C-DFs, while C-DFs expressed higher levels of cytokeratin (KRT14, KRT17, and KRT8) than CV-DFs. Moreover, all three types of DFs showed the ability to differentiate into chondrogenic, osteogenic, adipogenic, and myogenic cells. This study showed that there was a difference in the expression of cell markers, stemness factors, and differentiation potential between DFs and MSCs of different ethnic origin.[UPDATE] Ancient Chinese ruins on show to UK tourists Published duration 2 July 2015 media caption Archaeologist at Qin Shi Huang's tomb Ancient Chinese ruins are to be on display to foreign tourists for the first time. The 3,500-year-old sights on the northern plains are close to the capital, Beijing. They are also on private property, and are some of the least visited sites in the Chinese capital. Many of these sites were listed as "Protected Historic Monuments" until 2006. "These ancient sites are all near the
